**Course Code:CSA1709**  
**Course Name:Artificial Intelligence**

**Exp :21 Write a Prolog Program to implement Towers of Hanoi.**

**Aim:** To Write a Prolog Program to implement Towers of Hanoi.

**Algorithm:**

- Step 1: Define the main rule to initiate the problem, specifying the initial number of disks, the starting source peg (left), the final destination peg (right), and the auxiliary peg (center).
- Step 2: Define the base case where moving exactly 1 disk requires simply transferring it directly from the source peg to the destination peg and displaying the move.
- Step 3: Define the recursive rule for moving N disks (where N is greater than 1).
- Step 4: Calculate the value of N-1 to represent the smaller stack of disks above the largest disk.
- Step 5: Recursively move the top N-1 disks from the source peg to the auxiliary peg, utilizing the destination peg as a temporary holder.
- Step 6: Transfer the remaining 1 (largest) disk directly from the source peg to the destination peg and display the action.
- Step 7: Recursively move the N-1 disks from the auxiliary peg to the final destination peg, utilizing the source peg as a temporary holder.

**PROGRAM:**

hanoi(N) :-  
    move(N, left, right, center).

% Base Case: Moving 1 disk is simple. Just move it from Source to Destination.

```
move(1, Source, Destination, _) :-  
    write('Move top disk from '),  
    write(Source),  
    write(' to '),  
    write(Destination),  
    nl.
```

% Recursive Step: Moving N disks (where N > 1).

```
move(N, Source, Destination, Auxiliary) :-  
    N > 1,  
    M is N - 1,  
    % Step 1: Move N-1 disks from Source to Auxiliary peg  
    move(M, Source, Auxiliary, Destination),
```

```
    % Step 2: Move the remaining 1 (largest) disk from Source to Destination  
    move(1, Source, Destination, _),
```

```
    % Step 3: Move the N-1 disks from the Auxiliary peg to the Destination peg  
    move(M, Auxiliary, Destination, Source).
```

## OUTPUT:

A screenshot of a GNU Prolog console window. The window title is "GNU Prolog console". The menu bar includes "File", "Edit", "Terminal", "Prolog", and "Help". The text in the console shows the version "GNU Prolog 1.5.0 (64 bits)", compilation details "Compiled Jul 8 2021, 12:33:56 with cl", and copyright "Copyright (C) 1999-2021 Daniel Diez". It then shows the compilation of "C:/Users/DELL/OneDrive/Desktop/Documents/hanoi\_prob.pl for byte code...". The execution of the program "hanoi(3)." results in seven moves: "Move top disk from left to right", "Move top disk from left to center", "Move top disk from right to center", "Move top disk from left to right", "Move top disk from center to left", "Move top disk from center to right", and "Move top disk from left to right". The prompt "true ? |" is visible at the bottom.

**RESULT:** Thus, the program was executed and found that the output was found to be correct.

### **Exp :22 Write a Prolog Program to print particular bird can fly or not. Incorporate required queries.**

**Aim:** To write a Prolog program to determine whether a particular bird can fly or not by defining facts, exceptions, and logical rules.

#### **Algorithm:**

- Step 1: Define a set of facts declaring various entities as birds (e.g., sparrow, penguin, eagle).
- Step 2: Define another set of facts declaring the specific exceptions, i.e., birds that are known to be flightless.
- Step 3: Define a logical rule `can_fly(X)` which states that an entity `X` can fly if it is a bird AND it is not listed as flightless.
- Step 4: Load the knowledge base into the Prolog compiler.
- Step 5: Execute queries passing the name of the bird to determine its flying status based on the defined rules.

#### **Program:**

```
bird(sparrow).  
bird(eagle).  
bird(parrot).  
bird(pigeon).  
bird(penguin).  
bird(ostrich).  
bird(kiwi).
```

```
flightless(penguin).  
flightless(ostrich).  
flightless(kiwi).
```

```
can_fly(X) :-
```

```
bird(X),
\+ flightless(X).
```

### Output:

### Exp :23 Write the prolog program to implement family tree.

#### Aim:

To Write the prolog program to implement family tree.

#### Algorithm:

Step 1: Define basic facts to establish the gender of individuals using male(X) and female(X).

Step 2: Define basic facts to establish direct parent-child relationships using parent(X, Y) where X is the parent of Y.

Step 3: Define a logical rule for father(X, Y) specifying that X must be male and X must be a parent of Y.

Step 4: Define a logical rule for mother(X, Y) specifying that X must be female and X must be a parent of Y.

Step 5: Define a logical rule for sibling(X, Y) specifying that X and Y must share a common parent Z, and X must not be the same person as Y.

Step 6: Define a logical rule for grandparent(X, Y) by stating that X is the parent of Z, and Z is the parent of Y.

Step 7: Define additional specific rules such as brother, sister, grandfather, and grandmother by combining gender facts with the relationship rules.

Step 8: Load the program into the Prolog environment and execute queries to infer relationships from the knowledge base.

#### Program:

%Define males, females, and parent-child relationships

```
% male(Person)
male(john).
male(mark).
male(bob).
male(tom).
male(peter).
```

```
% female(Person)
female(mary).
female(susan).
female(alice).
female(linda).
female(jane).
```

```
% parent(Parent, Child)

## Exp :24 Write a Prolog Program to suggest Dieting System based on Disease.

### Aim:

To write a Prolog program that suggests an appropriate dieting system and dietary restrictions based on a patient's diagnosed disease.

### Algorithm:

Step 1: Define facts specifying the diseases diagnosed for different patients.

Step 2: Define facts detailing the recommended diet plans corresponding to various diseases.

Step 3: Define facts listing the specific foods to avoid for each respective disease.

Step 4: Create a logical rule that links a patient to their disease, the recommended diet, and the restricted foods.

Step 5: Load the code into the Prolog compiler.

Step 6: Execute queries to retrieve customized dietary recommendations for a specific patient or disease.

### Program:

```
disease(john, diabetes).
```

```
disease(mary, hypertension).
```

```
disease(alice, celiac).
```

```
disease(bob, obesity).
```

```
diet_for(diabetes, low_carbohydrate_and_sugar_free).

### **Exp :25 Write a Prolog program to implement Monkey Banana Problem**

#### **Aim:**

To write a Prolog program to solve the Monkey and Banana problem by defining states and possible moves to reach the goal state.

#### **Algorithm:**

- Step 1: Define the state structure as state(MonkeyPosition, MonkeyElevation, BoxPosition, HasBanana).
- Step 2: Establish the goal state where the monkey has grasped the banana state(., ., ., has).
- Step 3: Define the move rule for the "grasp" action, allowing the monkey to grasp the banana if it is on the box at the middle of the room.
- Step 4: Define the move rule for the "climb" action, allowing the monkey to step onto the box if both are at the same location on the floor.
- Step 5: Define the move rule for the "push" action, allowing the monkey to push the box from one location to another if they are together on the floor.
- Step 6: Define the move rule for the "walk" action, allowing the monkey to move independently from one location to another while on the floor.
- Step 7: Create a recursive canget rule that checks if the goal state is already achieved.
- Step 8: If the goal is not achieved, the canget rule tries a valid move to transition into a new state and recursively calls itself until it reaches the goal.

#### **Program:**

```
% State representation: state(MonkeyPos, MonkeyElev, BoxPos, HasBanana)

% 1. The monkey can grasp the banana if it is on the box in the middle of the room.
move(state(middle, onbox, middle, hasnot), grasp, state(middle, onbox, middle, has)).

% 2. The monkey can climb onto the box if they are at the same position.
move(state(Position, onfloor, Position, HasBanana), climb, state(Position, onbox, Position, HasBanana)).

% 3. The monkey can push the box from P1 to P2 if they are at the same position.
move(state(P1, onfloor, P1, HasBanana), push(P1, P2), state(P2, onfloor, P2, HasBanana)).

% 4. The monkey can walk from P1 to P2.
move(state(P1, onfloor, BoxPos, HasBanana), walk(P1, P2), state(P2, onfloor, BoxPos, HasBanana)).

% Base Case: The monkey already has the banana.
canget(state(., ., ., has)).

% Recursive Step: The monkey applies a valid move to reach a new state, and repeats.
canget(State1) :-
    move(State1, _, State2),
    canget(State2).
```

## OUTPUT:

```

**RESULT:** Thus, the program was executed and found that the output was found to be correct.

### Exp :26 Exp :24 Write a Prolog Program to suggest Dieting System based on Disease.

#### Aim:

To write a Prolog program that maps various fruits to their respective colors and demonstrates the concept of backtracking to retrieve multiple solutions for a single query.

#### Algorithm:

Step 1: Define a series of facts in the knowledge base linking a specific fruit to its color using the structure `color(Fruit, Color)`.

Step 2: Create multiple facts sharing the same color (e.g., apple is red, cherry is red) to allow for multiple possible matches.

Step 3: Define a basic rule `fruit_of_color(Fruit, Color)` that queries the color facts.

Step 4: Load the program into the Prolog compiler.

Step 5: Execute a query containing a variable (e.g., asking for all fruits that are 'red').

Step 6: Prolog finds the first matching fact and binds the variable. When the user requests alternative solutions (using `;`), Prolog applies backtracking—it undoes the variable binding, goes back up the search tree, and looks for the next matching fact until all possibilities are exhausted.

#### Program:

```
color(apple, red).
color(banana, yellow).
color(strawberry, red).
color(grape, purple).
color(cherry, red).
color(lemon, yellow).
color(watermelon, green).
color(lime, green).
```

```
fruit_of_color(Fruit, Color) :-
    color(Fruit, Color).
```

## OUTPUT:
